(Received October 26, 2005)

The dynamical response of a trapped Bose-Einstein condensate (BEC) is formulated consistently with quantum field theory and is numerically evaluated. We regard the BEC as a manifestation of the breaking of the global phase symmetry. Then, the Goldstone theorem implies the existence of a zero energy excitation mode (the zero-mode). We calculate the effect of the zero-mode on the response frequency and show that the contribution of the zero-mode to the first excitation mode is not so important in the parameter set realized in the existing experiment. This is the reason that experimental results can be described using the Bogoliubov prescription, although it breaks the consistency of the description in quantum field theory.

§1. Introduction

Since the experimental realization of the Bose-Einstein condensate (BEC) in trapped dilute atomic gases, a large number of works associated with trapped BECs have been reported. The majority of these works are devoted to the analysis of the Gross-Pitaevskii (GP) equation.¹⁾ The GP equation has been successful in accounting for experimental results at very low temperature.²⁾ However, the GP equation is not capable of describing the BECs as the temperature is raised, because, for instance, we should take the effect of the non-condensate fractions into account. Moreover, we can continue to fine-tune experiments on trapped BECs, changing the scattering length between atoms, by utilizing Feshbach resonance.³⁾ Thus, trapped BECs afford an opportunity for testing quantum field theory (QFT), which is still incomplete. To this end, we need to analyze trapped BECs beyond the GP equation.

There are several theoretical works in which the behavior of BECs at finite temperature both with^{4)–13)} and without a trapping potential^{16)–19)} is studied. In particular, the results given in Ref. 10), as well as Refs. 11)–13), are in good agreement with the experimental value¹⁴⁾ of the excitation frequencies from the low tempera-

†) E-mail: yamanaka@waseda.jp

ture region to the region near the transition temperature. The authors of Ref. 10) use Zaremba–Nikuni–Griffin formalism,¹⁵⁾ in which the time-dependent GP equation couples with the semiclassical Boltzmann equation. In Refs. 11)–13), the authors apply a time-dependent extension of the perturbation theory.

The quantization scheme of a trapped BEC is, however, an open question. From the viewpoint of QFT, the BEC is a manifestation of the spontaneous breakdown of a global phase symmetry. In this picture, the Goldstone theorem requires the existence of a mode with zero excitation energy (the zero-mode) for consistency with the fundamental concepts of QFT. However, a consistent quantization scheme is not easy to construct, because of, for instance, the problem of the infrared divergence. Usually, when the Bogoliubov prescription is employed, the zero-mode is ignored, but the naive application of the Bogoliubov prescription gives rise to inconsistency, because the precise canonical commutation relations cannot be satisfied. Thus, we cannot ignore the zero-mode in testing the predictions of quantum field theory in trapped BEC experiments.

Recently, a consistent quantization scheme was proposed by two of the present authors.²⁰⁾ They introduced an infinitesimal breaking term of the global phase symmetry. Here, the breaking term plays roles as a regulator of infrared divergences and enables us to construct the generalized Bogoliubov transformation (GBT) including the zero-mode.²⁰⁾ It has been proven that this mode corresponds to the Nambu-Goldstone (NG) mode by demonstrating that the Ward-Takahashi (WT) relations^{20),21)} are satisfied. Realization of unitarily inequivalent vacua that belong to order parameters with different phases was shown in Ref. 22). The existence of such vacua implies that the mechanism of the spontaneous symmetry breakdown works even in traps. There is another consistent field theoretical approach, in which the operators corresponding to the zero-mode are given by “quantum coordinates”.^{23),24)} The relation between the zero-mode approach and the quantum coordinate approach has been revealed,²⁵⁾ but it has not been confirmed that the WT relations are satisfied in the latter approach. It should also be mentioned that no definite criterion has been found for choosing quantum states acted on by quantum coordinates. Effects of the zero-mode, as well as modes represented by the quantum coordinates on the condensate density have been evaluated,^{20),26)} and, unfortunately, they were found to be too small to be detected in present-day experiments.

The aim of the consistent canonical studies cited above is to elucidate the equilibrium properties of trapped BECs.^{20)–26)} In this paper, we apply the consistent quantization scheme and study the effect of the zero-mode on the dynamical response of a trapped BEC at finite temperature.

This paper is organized as follows. In §2, we explain the quantization of a trapped BEC including the zero-mode. In §3, the dynamical response of the BEC under an external field is derived, and the results of numerical calculations are reported in §4. Section 5 contains concluding remarks. We give a brief summary of the mathematics regarding the GBT including the zero-mode in Appendix A.

§2. Quantization scheme consistent with the Goldstone theorem

In this section, we give a brief review of the quantization of a static trapped BEC including the zero-mode, following Refs. 21), 25) and 26).

We adopt the following action, which describes the dynamics of a neutral gas system trapped in a potential V :

$$S[\psi, \psi^\dagger] = \int dt d^3\mathbf{x} \left[\psi^\dagger(x) (T - K - V + \mu) \psi(x) - \frac{g}{2} \psi^{\dagger 2}(x) \psi^2(x) \right]. \quad (2.1)$$

Here, $T = i\frac{\partial}{\partial t}$, $K = -\frac{1}{2m}\nabla^2$, and μ and g denote the chemical potential and the coupling constant, respectively. We choose the harmonic trapping potential as $V = \frac{m}{2} \sum_{i=1}^3 \omega_i^2 x_i^2$, where ω_i is the trapping frequency along the x_i direction. The symbol x represents $(\mathbf{x}, t)$. For simplicity, we set $\hbar = 1$ throughout this paper.

This action is invariant under the global phase transformation

$$\psi(x) \rightarrow e^{i\eta} \psi(x) \quad \text{and} \quad \psi^\dagger(x) \rightarrow e^{-i\eta} \psi^\dagger(x), \quad (2.2)$$

where η is an arbitrary constant phase. The Bose-Einstein transition can be regarded as the spontaneous symmetry breaking associated with this phase transformation.

Usually, the action (2.1) is the basis of the quantization of trapped BEC systems. However, in analogy to the Ising model, we add the following artificial symmetry breaking term to Eq. (2.1):

$$\Delta S[\psi, \psi^\dagger] = \varepsilon \bar{\varepsilon} \int dt d^3x \left[e^{-i\theta} v(\mathbf{x}) \psi(x) + e^{i\theta} v(\mathbf{x}) \psi^\dagger(x) \right]. \quad (2.3)$$

Here, $\bar{\varepsilon}$ denotes a typical energy scale of the system determined by trapping frequencies. The infinitesimal parameter ε is taken to be vanishing at end of the calculation. This term is necessary to control the infrared divergence.²⁰⁾ The order parameter $e^{i\theta} v(\mathbf{x})$ is determined by a consistent procedure.

Now we consider canonical formalism. The quantized field satisfies the CCRs

$$[\hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)] = \delta^{(3)}(\mathbf{x} - \mathbf{x}'), \quad (2.4)$$

$$[\hat{\psi}(\mathbf{x}, t), \hat{\psi}(\mathbf{x}', t)] = [\hat{\psi}^\dagger(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)] = 0, \quad (2.5)$$

where the symbol $\hat{}$ indicates that quantities with it are regarded as operators. Corresponding to the breakdown of the global phase symmetry, we divide the original field $\hat{\psi}(x)$ into the classical and quantum parts, as

$$\hat{\psi}(x) = e^{i\theta} v(\mathbf{x}) + e^{i\theta} \hat{\varphi}(x). \quad (2.6)$$

Here, the time-independent real function $v(\mathbf{x})$ is a condensate field that breaks the global phase symmetry defined by Eq. (2.2). Thus, $v(\mathbf{x})$ is the order parameter of the BEC transition. It should be noted that $|v(\mathbf{x})|^2$ gives the number density of the condensate particles. It is assumed that the real number θ is independent of both time and space, corresponding to the situation without vortices.^{*)} In this case,

^{*)} When we consider a vortex, the phase depends on the space coordinates.

without loss of generality, we can set $\theta = 0$. From the CCRs of $\hat{\psi}$ and $\hat{\psi}^\dagger$, (2.4) and (2.5), the CCRs of $\hat{\varphi}$ and $\hat{\varphi}^\dagger$ are given by

$$[\hat{\varphi}(\mathbf{x}, t), \hat{\varphi}^\dagger(\mathbf{x}', t)] = \delta^{(3)}(\mathbf{x} - \mathbf{x}'), \quad (2.7)$$

$$[\hat{\varphi}(\mathbf{x}, t), \hat{\varphi}(\mathbf{x}', t)] = [\hat{\varphi}^\dagger(\mathbf{x}, t), \hat{\varphi}^\dagger(\mathbf{x}', t)] = 0. \quad (2.8)$$

Calculating the Hamiltonian corresponding to the total action $S + \Delta S$, and substituting Eq. (2.6) into it, we obtain

$$\hat{H} = \hat{H}_0 + \hat{H}_I, \quad (2.9)$$

where

$$\hat{H}_0 = \int d^3\mathbf{x} \left[\hat{\varphi}^\dagger(K + V - \mu)\hat{\varphi} + \frac{gv^2}{2}(4\hat{\varphi}^\dagger\hat{\varphi} + \hat{\varphi}^2 + \hat{\varphi}^{\dagger 2}) \right], \quad (2.10)$$

$$\begin{aligned} \hat{H}_I = \int d^3\mathbf{x} & \left[v(K + V - \mu + gv^2 - \varepsilon\bar{\varepsilon})\hat{\varphi} + \hat{\varphi}^\dagger(K + V - \mu + gv^2 - \varepsilon\bar{\varepsilon})v \right. \\ & \left. + gv(\hat{\varphi}^\dagger\hat{\varphi}^\dagger\hat{\varphi} + \hat{\varphi}^\dagger\hat{\varphi}\hat{\varphi}) + \frac{g}{2}\hat{\varphi}^\dagger\hat{\varphi}^\dagger\hat{\varphi}\hat{\varphi} \right]. \end{aligned} \quad (2.11)$$

Here, we have dropped the constant term independent of $\hat{\varphi}$ and $\hat{\varphi}^\dagger$.

Now we adopt the Hartree-Fock-Bogoliubov approximation, in which the third- and fourth-order terms of $\hat{\varphi}$ and $\hat{\varphi}^\dagger$ are replaced as follows:

$$\hat{\varphi}^\dagger\hat{\varphi}^\dagger\hat{\varphi} \longrightarrow \langle \hat{\varphi}^\dagger\hat{\varphi}^\dagger \rangle \hat{\varphi} + 2\hat{\varphi}^\dagger \langle \hat{\varphi}^\dagger\hat{\varphi} \rangle, \quad (2.12a)$$

$$\hat{\varphi}^\dagger\hat{\varphi}\hat{\varphi} \longrightarrow 2\langle \hat{\varphi}^\dagger\hat{\varphi} \rangle \hat{\varphi} + \hat{\varphi}^\dagger \langle \hat{\varphi}\hat{\varphi} \rangle, \quad (2.12b)$$

$$\hat{\varphi}^\dagger\hat{\varphi}^\dagger\hat{\varphi}\hat{\varphi} \longrightarrow 4\langle \hat{\varphi}^\dagger\hat{\varphi} \rangle \hat{\varphi}^\dagger\hat{\varphi} + \langle \hat{\varphi}^{\dagger 2} \rangle \hat{\varphi}^2 + \langle \hat{\varphi}^2 \rangle \hat{\varphi}^{\dagger 2}. \quad (2.12c)$$

Here, $\langle \rangle$ represents the thermal expectation value, which will be determined self-consistently using the mean-field approximated Hamiltonian $\hat{H}_{\text{MFA}}$, and which is defined through the relation $\langle \hat{O} \rangle = \text{Tr}[e^{-\beta\hat{H}_{\text{MFA}}} \hat{O}] / Z$ with $Z = \text{Tr}[e^{-\beta\hat{H}_{\text{MFA}}}]$, where $\hat{O}$ is any operator. We further employ the Popov approximation and drop the terms proportional to $\langle \hat{\varphi}^2 \rangle$ and $\langle \hat{\varphi}^{\dagger 2} \rangle$ ²⁸⁾ in order to ensure a gapless spectrum.^{*)} Finally, the Hamiltonian is reduced to

$$\begin{aligned} \hat{H}_{\text{MFA}} = \int d^3\mathbf{x} & \left[\hat{\varphi}^\dagger(K + V - \mu + 2gv^2 + 2g\langle \hat{\varphi}^\dagger\hat{\varphi} \rangle)\hat{\varphi} + \frac{g}{2}\hat{\varphi}^2v^2 + \frac{g}{2}\hat{\varphi}^{\dagger 2}v^2 \right. \\ & + v(K + V - \mu + gv^2 - \varepsilon\bar{\varepsilon} + 2g\langle \hat{\varphi}^\dagger\hat{\varphi} \rangle)\hat{\varphi} \\ & \left. + \hat{\varphi}^\dagger(K + V - \mu + gv^2 - \varepsilon\bar{\varepsilon} + 2g\langle \hat{\varphi}^\dagger\hat{\varphi} \rangle)v \right]. \end{aligned} \quad (2.13)$$

^{*)} For a homogeneous system, it has been proven that in the thermodynamic limit, if one performs a second-order perturbative calculation, the Hugenholtz-Pines (HP) theorem,²⁹⁾ which ensures the global gauge invariance, holds.³⁰⁾ There is yet no similar proof for a trapped system. Recently, it has been shown³¹⁾ that the HP theorem holds for the loop expansion in the case of a finite volume system without a trapping potential but with periodic boundary conditions even without taking the thermodynamic limit.

The terms first-order in $\hat{\varphi}$ and $\hat{\varphi}^\dagger$ should vanish. Thus, the condensate v satisfies

$$(K + V - \mu + gv^2 - \varepsilon\bar{\varepsilon} + 2g\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle)v = 0. \quad (2.14)$$

This equation is identical to the GP equation¹⁾ in the limit $\epsilon \rightarrow 0$.

Because the von Neumann theorem does not hold in QFT, there are many Fock spaces that are orthogonal to each other,²²⁾ and we need to choose a physical Fock space among them. Here, we adopt the procedure proposed by two of the present authors,²⁰⁾ in which the physical Fock space is defined by the vacuum of annihilation operators defined by diagonalizing $\hat{H}_{\text{MFA}}$ using the GBT.^{21), 25), 26)}

First, we prepare an orthonormal set $\{w_n(\mathbf{x})\}$ obtained by solving the differential equation

$$\left(K + V - \mu + gv^2 + 2g\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle\right)w_n(\mathbf{x}) = (\epsilon_n + \varepsilon\bar{\varepsilon})w_n(\mathbf{x}). \quad (2.15)$$

The orthonormal and completeness conditions of this set are

$$\int d^3\mathbf{x} w_n(\mathbf{x})w_{n'}(\mathbf{x}) = \delta_{nn'}, \quad (2.16a)$$

$$\sum_{n=0}^{\infty} w_n(\mathbf{x})w_n(\mathbf{x}') = \delta^{(3)}(\mathbf{x} - \mathbf{x}'). \quad (2.16b)$$

Then, the field operators $\hat{\varphi}(\mathbf{x})$ and $\hat{\varphi}^\dagger(\mathbf{x})$ are expanded as

$$\hat{\varphi}(\mathbf{x}) = \sum_{n=0}^{\infty} [\hat{b}_n w_{Cn}(\mathbf{x}) - \hat{b}_n^\dagger w_{Sn}(\mathbf{x})], \quad (2.17a)$$

$$\hat{\varphi}^\dagger(\mathbf{x}) = \sum_{n=0}^{\infty} [\hat{b}_n^\dagger w_{Cn}(\mathbf{x}) - \hat{b}_n w_{Sn}(\mathbf{x})], \quad (2.17b)$$

where

$$w_{Cn}(\mathbf{x}) = \sum_{m=0}^{\infty} C_{nm} w_m(\mathbf{x}), \quad (2.18)$$

$$w_{Sn}(\mathbf{x}) = \sum_{m=0}^{\infty} S_{nm} w_m(\mathbf{x}). \quad (2.19)$$

The matrices C and S are introduced in association with the GBT that diagonalizes $\hat{H}_{\text{MFA}}$. (See Appendix A for details.) Note that C and S are singular in the limit $\epsilon \rightarrow 0$ and give rise to an infrared divergence.

Finally, the Hamiltonian $\hat{H}_{\text{MFA}}$ is diagonalized as follows:

$$\hat{H}_{\text{MFA}} = \sum_{n=0}^{\infty} E_n \hat{b}_n^\dagger \hat{b}_n + \text{const}, \quad (2.20)$$

where the quasiparticle energies E_n depend on $\{w_n(\mathbf{x})\}$, $v(\mathbf{x})$ and $\{\epsilon_n\}$, and its expression is given in Appendix A. It should be noted that the energies E_n are finite even after taking the limit of $\epsilon \rightarrow 0$. Finally, the physical vacuum is defined by

$$\hat{b}_n|0\rangle = 0. \quad (2.21)$$

The creation and annihilation operators satisfy the bosonic commutation relations

$$[\hat{b}_n, \hat{b}_{n'}^\dagger] = \delta_{nn'}, \quad (2.22)$$

with all other commutators vanishing. Thus, the quantization scheme explained here satisfies the CCRs (2.7) and (2.8) precisely, in contrast to the Bogoliubov prescription. This is because the mode associated with E_0 is not included in the field expansion in the Bogoliubov prescription.

§3. Dynamical treatment of a system under an external perturbation

To this point, we have studied the quantization scheme in a static system. In this section, we discuss the dynamical behavior of a BEC.

To investigate the response to an external field, we introduce the time-dependent external perturbation

$$\hat{H}_{\text{ex}}(t) = \int d^3\mathbf{x} \hat{\psi}^\dagger(\mathbf{x}) \delta V(\mathbf{x}, t) \hat{\psi}(\mathbf{x}), \quad (3.1)$$

where

$$\delta V(\mathbf{x}, t) = \frac{m}{2} \sum_{i=1}^3 \delta \omega_i^2(t) x_i^2. \quad (3.2)$$

Then, the total trapping potential is given by

$$V_{\text{ex}}(\mathbf{x}, t) \equiv V(\mathbf{x}) + \delta V(\mathbf{x}, t). \quad (3.3)$$

The Heisenberg equation of motion with a time-dependent perturbation is given by

$$i \frac{\partial}{\partial t} \hat{\psi}_{\text{ex}} = (K + V_{\text{ex}}(\mathbf{x}, t) - \mu - \varepsilon \bar{\varepsilon} + g \hat{\psi}_{\text{ex}}^\dagger \hat{\psi}_{\text{ex}}) \hat{\psi}_{\text{ex}}, \quad (3.4)$$

where $\hat{\psi}_{\text{ex}}$ denotes the boson operator subject to the perturbation. As in the preceding section, we separate $\hat{\psi}_{\text{ex}}$ into two terms as follows:

$$\hat{\psi}_{\text{ex}}(x) = v_{\text{ex}}(\mathbf{x}, t) + \hat{\varphi}(x). \quad (3.5)$$

We further employ the Hartree-Fock-Bogoliubov-Popov (HFBP) approximation. Then the GP equation becomes

$$i \frac{\partial}{\partial t} v_{\text{ex}} = (K + V_{\text{ex}} - \mu - \varepsilon \bar{\varepsilon} + g |v_{\text{ex}}|^2 + 2g \langle \hat{\varphi}^\dagger \hat{\varphi} \rangle_{\text{ex}}) v_{\text{ex}}, \quad (3.6)$$

where $|v_{\text{ex}}|^2$ is the number distribution of the condensate particles. Now, the order parameter has an explicit time dependence, in contrast to the static case.

However, Eq. (3.6) is still difficult to solve, because we must redefine a physical Fock space with the time evolution of the condensate. If we are interested in low temperature and/or weak coupling systems in which fluctuations are expected to be

small, however, we can further linearize the equation about the equilibrium values. Thus, the condensate field and the number density of the excited particles, $\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle_{\text{ex}}$, are expanded about the static quantities defined in the preceding section,

$$v_{\text{ex}}(x) = v(\mathbf{x}) + \delta v(x), \quad (3.7)$$

$$\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle_{\text{ex}} = \langle\hat{\varphi}^\dagger\hat{\varphi}\rangle + \delta\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle. \quad (3.8)$$

Keeping the first-order terms $\delta V(x)$, $\delta v(x)$ and $\delta\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle$ and ignoring the higher-order terms, we obtain the linearized equation. It should be noted that the linear approximation with the HFBP approximation can be regarded as the time-dependent linearized Hartree approximation, and this approximation is known to be equivalent to the random phase approximation (RPA). Thus, this approach contains fluctuations beyond the mean-field approximation. To obtain further simplicity, we may ignore the term proportional to $\delta\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle$, because the quantity $\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle$ is already very small. Finally, we obtain

$$i\frac{\partial}{\partial t}\delta v(x) = \left(K + V - \mu + 2gv^2 + 2g\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle\right)\delta v(x) + gv^2\delta v^*(x) + \delta V(x)v. \quad (3.9)$$

Note that the phase of the condensate field is time dependent. Thus, this equation can in principle describe vortex formation.

The effect of the zero-mode is included in $\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle$. Thus, it possesses infrared divergence, because of the singularity of S and C .^{(21), (25), (26)} To avoid this difficulty, we employ the renormalization criterion according to which all terms proportional to $u_0^2(\mathbf{x})$ are ignored. It should be noted that we still keep the terms proportional to $u_l(\mathbf{x})u_0(\mathbf{x})$ ($l \neq 0$) in the limit of $\epsilon \rightarrow 0$. Thus, the nontrivial effect attributed to the zero-mode is still taken into account.

§4. Numerical study

In this section, we report the results of our numerical study of Eq. (3.9). In this study, we chose the parameter values so as to reproduce the experimental situation.⁽¹⁴⁾

4.1. Thermal particle density

According to Eq. (3.9), the time evolution of the condensate is affected by the thermal non-condensate particle density $\langle\hat{\varphi}^\dagger\hat{\varphi}\rangle$. First, we study the effect of the zero-mode on the non-condensate particle. For simplicity, we treat a spatially one-dimensional system and consider the BEC of rubidium atoms, ^{87}Rb , whose mass is $m = 1.42 \times 10^{-25}\text{kg}$, and set the frequency of the trapping potential as $\omega_1 = 200 \times 2\pi\text{Hz}$. Here, we set the parameter values as $T/T_c = 7.3 \times 10^{-2}$, $g = 0.02$ in oscillator units (HO units), with the condensed atom number $N_c = 1000$. Here, T_c is the transition temperature of an ideal Bose gas in a one-dimensional system, whose value is $T_c = \frac{\omega_1}{k_B} \frac{N}{\ln 2N} = 8.3 \times 10^{-6}\text{K}$, according to the estimation given in Ref. 34), where k_B is the Boltzmann constant and N is the total number of atoms, which in our calculations is $N = 1068$. The numerical calculations were carried out in the following steps. First, we diagonalized the mean field Hamiltonian $\hat{H}_{\text{MFA}}$ (2.13) under

Fig. 1. Thermal particle densities of the one-dimensional system, with the parameter values $T/T_c = 7.3 \times 10^{-2}$, $g = 0.02$ (HO units). The solid curve represents the result with the zero-mode, while the dotted curve represents the result without it.

the condition (2.14) to define the physical Fock space. Accordingly, we estimated the expectation value $\langle \hat{\varphi}^\dagger \hat{\varphi} \rangle$.

Figure 1 plots this thermal particle density, calculated both with and without the zero-mode. The solid and dashed curves represent the thermal particle density with and without the zero-mode, respectively. One can clearly see that the density of the thermal particles increases around $x = 0$, because of the zero-mode. This difference is, however, very small compared to the condensate number density, because the thermal particle density is about two orders smaller than the condensate particle density in our calculation. Thus, it is still not clear whether the zero-mode can significantly affect the dynamical response of the condensate field.

4.2. Time evolution of the condensate

The actual experiment was carried out in a cylindrically symmetric system. However, we assume spherical symmetry here for calculational simplicity. Then, the static trap potential with frequency $\omega \equiv \omega_i$ ($i = 1, 2, 3$) and the corresponding external perturbation are given by

$$V(r) = \frac{1}{2} m \omega^2 r^2, \quad (4.1)$$

$$\delta V(r, t) = \frac{1}{2} m \delta \omega^2(t) r^2, \quad (4.2)$$

respectively. In conformity with the experiment,¹⁴⁾ we employed the following time-dependent frequency:

$$\delta \omega^2(t) = \omega^2 A \sin \Omega t. \quad (4.3)$$

The quantities A and Ω are the driving amplitude and the driving frequency, respectively.

Fig. 2. Time evolution of the condensate with the parameter values $T/T_c = 0.11$, $A = 0.01$, $\Omega = 1.3$ (HO units). The expression “perturb off” refers to the time at which the perturbation is turned off. After that time, the condensate oscillates sinusoidally with an amplitude of 0.3 % with respect to the initial size.

The numerical calculation was carried out in the following steps. First, we estimated the expectation value $\langle \hat{\varphi}^\dagger \hat{\varphi} \rangle$, using the procedure described in the previous subsection, and solved Eq. (3.9). The parameter values were chosen so as to reproduce the trapped atoms of ^{87}Rb , where $m = 1.42 \times 10^{-25}\text{kg}$, $\omega = 200 \times 2\pi\text{Hz}$ and $g = 0.03$ in HO units and condensed atom number is $N_c = 1000$. The temperature T , in units of T_c , the driving amplitude A , and the driving frequency Ω are the control parameters in the experiment, where $T_c = 0.94 \frac{\omega}{k_B} N^{1/3}$ is the critical temperature of the ideal Bose gas confined in a three-dimensional spherically symmetric trap.²⁾ The value of T_c is approximately 100 nK in this calculation.

In Fig. 2, we plot the time evolution of the size of the condensate, defined by

$$\sqrt{\langle r^2 \rangle} = \sqrt{\frac{\int r^2 |v_{\text{ex}}|^2 d^3\mathbf{x}}{\int |v_{\text{ex}}|^2 d^3\mathbf{x}}} . \quad (4.4)$$

The temperature, the driving amplitude and the driving frequency are given by $T/T_c = 0.11$, $A = 0.01$ and $\Omega = 1.3$ (HO units), respectively. Under the external perturbation, we observe beat-like behavior. The external perturbation was turned off at about 15.4 ms, which is a typical value in the corresponding experiment.¹⁴⁾ Then, the frequency of the oscillation of the condensate is 2.014 (HO units). This frequency characterizes the dynamical behavior of the condensate. We plot the numerical result with a different driving frequency, $\Omega = 2.0$ (HO units), in Fig. 3. After turning off the external perturbation, the frequency of the oscillation of the condensate is again given by 2.014 (HO units). It should be noted that the resonance gives rise to an increase of the amplitude, and we verified that the amplitude is maximized at $\Omega = 2.014$ (HO units).

The first excitation energy of the quasiparticle is $E_1 = 2.014$ (HO units) [see Eq. (2.20)]. It is thus seen that the frequency of the oscillation is characterized by the

Fig. 3. Time evolution of the condensate with the parameter values $T/T_c = 0.11$, $A = 0.01$, $\Omega = 2.0$ (HO units). The amplitude of the oscillation is 4.5 % with respect to the initial size.

first excitation energy of the quasiparticle. This result is consistent with that of the linear density response.³³⁾

4.3. Temperature dependence of the response frequency and the effect of the zero-mode

In the preceding section, we showed that it is possible to extract information concerning the first excitation energy of the quasiparticle through the frequency of the oscillation. In this section, we investigate the effect of the zero-mode on the frequency.

In Table I, the temperature dependence of the frequency is described for two cases, those in which the frequencies are calculated with the zero-mode and those without the zero-mode. The driving amplitude and the driving frequency are given by $A = 0.01$ and $\Omega = 2.0$ (HO units), respectively. The table lists the temperature, the frequency with the zero-mode, that without the zero-mode, and the difference between these two frequencies. It can be seen that the effect of the zero-mode on the response frequency is very small. This is consistent with the fact that the properties of a trapped BEC at low temperature are described in the Bogoliubov prescription, although it violates the CCRs. It is also seen that the frequency decreases as the temperature is increased. It follows that the first excitation energy is lowered by the influence of the medium effect. Thus, the energy shift due to the zero-mode becomes important as the temperature is increased. However, the magnitude of this shift is still very small, and the effect of the zero-mode is negligible for this set of parameter values.

4.4. Coupling dependence of the first excitation energy and the effect of the zero-mode

In the preceding subsection, we showed that the effect of the zero-mode in the experiment reported in Ref. 14) is quite small and does not affect the properties of

the trapped BEC system. The merit of the trapped BEC experiment is that we can change the magnitude of the coupling constant by using the Feshbach resonance.³⁾ Thus, the effect of the zero-mode may be experimentally observed with other set of parameter values. In this section, we investigate the coupling constant dependence of the zero-mode.

We again assume an one-dimensional system and consider a BEC of rubidium atoms, ^{87}Rb . The parameter values are the same as in §§4.1. Here, we simply calculate the first excitation energy, which corresponds to the dipole mode. This is an ideal one-dimensional calculation, and it does not correspond directly to the experiments.

Table II. Temperature and coupling constant dependences of the first excitation energy including the zero-mode.

T/T_c	first excitation energy		
	$g=0.01$	$g=0.015$	$g=0.02$
1.5×10^{-2}	1.0033	1.0454	1.0749
3.7×10^{-2}	1.0685	1.1243	1.1908
7.3×10^{-2}	1.143	1.243	1.350

Table III. Temperature and coupling constant dependences of the subtraction of the frequency without the zero-mode from that that with the zero-mode.

T/T_c	difference		
	$g=0.01$	$g=0.015$	$g=0.02$
1.5×10^{-2}	0.0007	0.0020	0.0037
3.7×10^{-2}	0.0022	0.0046	0.0088
7.3×10^{-2}	0.004	0.008	0.013

Table II lists the temperature and coupling constant dependences of the first excitation energy including the zero-mode. We can see that this energy becomes larger as we increase not only the temperature but also the coupling constant. The difference^{*)} is listed in Table III. ^{**) However, our numerical results exhibit deviation from Kohn's theorem,³²⁾ according to which the energy of the dipole mode should be 1. This seems}

to be due to the fact that the dynamics of the non-condensate field are not properly taken into account. As a matter of fact, the deviation becomes larger as the temperature is increased. Thus, the effect of the zero-mode observed here is not

*) The definition of this quantity is the same as that given in Table I.

**) The coupling constant g used here is smaller than 0.03, the value used in the calculations in the preceding subsections. Note that the spatial dimension is 1 in this subsection, while it is 3 in §§4.2 and 4.3.

physical.

Table IV. Temperature and coupling constant dependences of the second excitation energy including the zero-mode.

T/T_c	second excitation energy		
	$g=0.01$	$g=0.015$	$g=0.02$
1.5×10^{-2}	1.7874	1.7873	1.7974
3.7×10^{-2}	1.8199	1.8409	1.8744
7.3×10^{-2}	1.875	1.928	1.991

Table V. Temperature and coupling constant dependences of the difference (second excitation energy).

T/T_c	difference		
	$g=0.01$	$g=0.015$	$g=0.02$
1.5×10^{-2}	0.0007	0.0018	0.0030
3.7×10^{-2}	0.002	0.004	0.008
7.3×10^{-2}	0.004	0.007	0.012

As we have discussed, the first excitation energy should be 1 for all temperatures and interactions, as asserted by Kohn's theorem. In order to determine the effect of the zero-mode, we should calculate the energy shift of the second excitation energy. Table IV lists the temperature and coupling constant dependence of the second excitation energy including the zero-mode, and the difference is listed

in Table V. It is seen that the effect of the zero-mode is enhanced as the temperature and the coupling constant are increased. However, by comparing with Table III, we see that the effect of the zero-mode on the second excitation energy is of almost the same order as that on the first excitation energy. Thus, there is a possibility that this effect vanishes when we make corrections in order to satisfy Kohn's theorem. In short, the effect of the zero-mode in the one-dimensional system is not yet clear.

§5. Concluding remarks

We have formulated the dynamical response of a trapped BEC including the zero-mode at low temperature, using the HFBP and linear approximations. The zero-mode appears as a NG mode associated with the global phase symmetry breaking. To take the zero-mode into account, we introduced the generalized Bogoliubov transformation following Ref. 20). We numerically calculated the dynamical response of the condensate by applying a time-dependent perturbation in the linear response

approximation. Thus, the fluctuations from the mean-field approximation are partially taken into account. The frequency of the condensate is determined by the first excitation energy of the quasiparticle. We observed that the presence of the zero-mode increases the frequency and hence the first excitation energy. With the parameter values used in the experiment,¹⁴⁾ the effect of the zero-mode on the first excitation energy is very small. Thus, we conclude that the properties of the trapped BEC in this region can be described by the Boboliubov prescription, although it leads to an inconsistent description in quantum field theory.

To determine the temperature and coupling constant dependences, we studied the first and second excitation energies in a one-dimensional system. From Kohn's theorem, it can be proved that the first excitation energy should be 1 for any temperature and interaction. Our results, however, exhibit deviation from 1. This deviation appears to be due to the inadequate approximation used for the non-condensate field, because the deviation becomes larger as the temperature is increased. The second excitation mode is also affected by the zero-mode. The magnitude of the energy shift is, however, almost the same as that of the first excitation energy. Thus, it is not clear whether the observed effect comes from the effect of the zero-mode or from the inadequate approximation violating Kohn's theorem.

To improve our results, we should take account of the fluctuations of the non-condensate field, which is dropped in Eq. (3.9). As a matter of fact, it has been reported that the collective dynamics of the non-condensate field play an important role.³⁵⁾ In our calculation, if we take the fluctuations of the non-condensate field into account, the approximation is equivalent to the time-dependent linear Hartree approximation, that is, the RPA, and we can expect that a collective mode like the plasmon in an electron gas will be included. However, the translational invariance is broken by the trapped potential in this system. Thus, the analysis of the collective mode is not simple, and we must introduce several approximations to simplify calculations.^{13),36)} The study of the effect of the fluctuations of the non-condensate field is a future problem.

In this paper, we have concentrated on elucidating the effect of the zero-mode on the first excitation energy. However, calculations of the temperature dependence of the condensate fractions and the specific heat are also interesting.

The effect of the gapless mode was also studied in Ref. 6). However, that work does not include the zero-mode in the non-condensate field. Consequently, the non-condensate field has zero projection on the condensate, and this property simplifies the calculation. By contrast, the zero-mode is included in the non-condensate field in our formalism. Thus, the gapless mode investigated in Ref. 6) is different from the zero-mode investigated here.

Appendix A

— Generalized Bogoliubov Transformation Including the Zero-Mode —

We have introduced the orthonormal set $\{w_n(\mathbf{x})\}$ satisfying Eq. (2.15) with the orthonormal and completeness conditions (2.16a) and (2.16b). It is easily seen that Eq. (2.15) reduces to the GP equation for $n = 0$ in the limit $\epsilon \rightarrow 0$, because we have $\epsilon_0 = 0$. The condensate field is given by

$$v(\mathbf{x}) = \sqrt{N_c} w_0(\mathbf{x}). \quad (\text{A}\cdot 1)$$

Using the orthonormal set, we expand $\hat{\varphi}(x)$ and introduce the creation and annihilation operators:

$$\hat{\varphi}(\mathbf{x}) = \sum_{n=0}^{\infty} \hat{a}_n w_n(\mathbf{x}). \quad (\text{A}\cdot 2)$$

The operators $\hat{a}_n$ and $\hat{a}_n^\dagger$ are subject to the condition

$$[\hat{a}_n, \hat{a}_{n'}^\dagger] = \delta_{nn'}, \quad (\text{A}\cdot 3)$$

with all other commutators vanishing: $[\hat{a}_n, \hat{a}_{n'}] = [\hat{a}_n^\dagger, \hat{a}_{n'}^\dagger] = 0$.

Substituting Eq. (A.2) into the mean field Hamiltonian (2.13) with the condition (2.14), we obtain

$$\hat{H}_{\text{MFA}} = \sum_{n=0}^{\infty} (\epsilon_n + \epsilon\bar{\epsilon}) \hat{a}_n^\dagger \hat{a}_n + \sum_{n,n'=0}^{\infty} \left[2U_{nn'} \hat{a}_n^\dagger \hat{a}_{n'} + U_{nn'} \hat{a}_n \hat{a}_{n'} + U_{nn'} \hat{a}_n^\dagger \hat{a}_{n'}^\dagger \right], \quad (\text{A}\cdot 4)$$

where

$$U_{nn'} = \frac{g}{2} \int d^3\mathbf{x} w_n(\mathbf{x}) w_{n'}(\mathbf{x}) v^2(\mathbf{x}). \quad (\text{A}\cdot 5)$$

The physical Fock space is defined by the creation and annihilation operators that diagonalize the mean field Hamiltonian. For this purpose, the following operators are introduced:

$$\hat{q}_n = \sqrt{\frac{1}{2(\epsilon_n + \epsilon\bar{\epsilon})}} (\hat{a}_n + \hat{a}_n^\dagger), \quad (\text{A}\cdot 6a)$$

$$\hat{p}_n = -i\sqrt{\frac{\varepsilon_n + \varepsilon\bar{\varepsilon}}{2}}(\hat{a}_n - \hat{a}_n^\dagger). \quad (\text{A}\cdot 6\text{b})$$

These operators satisfy the CCRs

$$[\hat{q}_n, \hat{p}_n] = i\delta_{nn'}. \quad (\text{A}\cdot 7)$$

All other commutators vanish.

Then, $\hat{H}_{\text{MFA}}$ can be rewritten as

$$\hat{H}_{\text{MFA}} = \sum_{n=0}^{\infty} \frac{1}{2} \hat{p}_n^2 + \sum_{n,n'=0}^{\infty} \frac{1}{2} \hat{q}_n W_{nn'} \hat{q}_{n'} - \sum_{n=0}^{\infty} \left[\frac{1}{2} (\varepsilon_n + \varepsilon\bar{\varepsilon}) + U_{nn'} \right]. \quad (\text{A}\cdot 8)$$

Here, the matrix W has a block structure,

$$W = \begin{pmatrix} 4(\varepsilon\bar{\varepsilon})U_{00} + O(\varepsilon^2) & \sqrt{\varepsilon\bar{\varepsilon}}u'^T + O(\varepsilon^{\frac{3}{2}}) \\ \sqrt{\varepsilon\bar{\varepsilon}}u' + O(\varepsilon^{\frac{3}{2}}) & W' + O(\varepsilon) \end{pmatrix}, \quad (\text{A}\cdot 9)$$

with

$$u' = \begin{pmatrix} 4\sqrt{\varepsilon_1}U_{10} \\ 4\sqrt{\varepsilon_2}U_{20} \\ \vdots \end{pmatrix}, \quad (\text{A}\cdot 10\text{a})$$

$$W'_{nm} = \varepsilon_n^2 \delta_{nm} + 4\sqrt{\varepsilon_n}U_{nm}\sqrt{\varepsilon_m}. \quad (\text{A}\cdot 10\text{b})$$

$(n, m = 1, 2, \dots)$

This symmetric matrix W can be diagonalized by using an orthogonal matrix $\mathcal{O}$ with eigenvalues E_n^2 ($n = 0, 1, 2, \dots$):

$$\mathcal{O}W\mathcal{O}^T = E^2, \quad (\text{A}\cdot 11)$$

with

$$(E)_{nm} = E_n \delta_{nm}. \quad (\text{A}\cdot 12)$$

The above expressions are expanded with respect to the infinitesimal parameter ε . It should be noted that the zero-th eigenvalue is given by

$$E_0 = \sqrt{\varepsilon\bar{\varepsilon}}\sqrt{\bar{E}_0} + O(\varepsilon^{\frac{3}{2}}), \quad (\text{A}\cdot 13\text{a})$$

$$\bar{E}_0 \equiv 4U_{00} - u'^T W'^{-1} u', \quad (\text{A}\cdot 13\text{b})$$

and it vanishes when we take the limit $\varepsilon \rightarrow 0$, but we keep it finite in the quantization procedure.

Then, the orthogonal matrix $\mathcal{O}$ can be written as

$$\mathcal{O} = \begin{pmatrix} 1 - \frac{1}{2}(\varepsilon\bar{\varepsilon})u'^T W'^{-2} u' + O(\varepsilon^2) & -\sqrt{\varepsilon\bar{\varepsilon}}u'^T W'^{-1} \mathcal{O}'^T + O(\varepsilon^{\frac{3}{2}}) \\ \sqrt{\varepsilon\bar{\varepsilon}}\mathcal{O}' W'^{-1} u' + O(\varepsilon^{\frac{3}{2}}) & \mathcal{O}' + O(\varepsilon) \end{pmatrix}, \quad (\text{A}\cdot 14)$$

where $\mathcal{O}'$ is another orthogonal matrix diagonalizing the matrix W' ,

$$\mathcal{O}'W'\mathcal{O}'^T = E'^2, \quad (\text{A}\cdot 15)$$

with the diagonal matrix

$$\left(E'^2\right)_{nm} = E_n^2 \delta_{nm} + O(\varepsilon^{\frac{1}{2}}). \quad (n, m = 1, 2, \dots) \quad (\text{A}\cdot 16)$$

Thus the mixing among $\hat{a}_n$ ($n = 1, 2, \dots$) is regular with respect to ε ; only the mixing between $\hat{a}_0$ and other $\hat{a}_n$ gives rise to a singularity.

By using the orthogonal matrix $\mathcal{O}$, we can introduce new pairs of canonical operators as

$$\hat{Q}_n = \sum_{m=0}^{\infty} \mathcal{O}_{nm} \hat{q}_m, \quad (\text{A}\cdot 17a)$$

$$\hat{P}_n = \sum_{m=0}^{\infty} \mathcal{O}_{nm} \hat{p}_m, \quad (\text{A}\cdot 17b)$$

with $[\hat{Q}_n, \hat{P}_{n'}] = i\delta_{nn'}$, while all other commutators vanish.

Finally, we can diagonalize the mean field Hamiltonian,

$$\begin{aligned} \hat{H}_{\text{MFA}} &= \sum_{n=0}^{\infty} \left[\frac{1}{2} \hat{P}_n^2 + \frac{1}{2} \hat{Q}_n^2 - \frac{1}{2} (\varepsilon_n + \varepsilon \bar{\epsilon}) + U_{nn'} \right] \\ &= \sum_{n=0}^{\infty} \left[E_n \hat{b}_n^\dagger \hat{b}_n + \frac{1}{2} E_n - \frac{1}{2} (\varepsilon_n + \varepsilon \bar{\epsilon}) + U_{nn'} \right]. \end{aligned} \quad (\text{A}\cdot 18)$$

In the second equality, the operators $\hat{Q}_n$ and $\hat{P}_n$ are related to $\hat{b}_n$ and $\hat{b}_n^\dagger$ as

$$\hat{Q}_n = \sqrt{\frac{1}{2E_n}} (\hat{b}_n + \hat{b}_n^\dagger), \quad (\text{A}\cdot 19a)$$

$$\hat{P}_n = -i\sqrt{\frac{E_n}{2}} (\hat{b}_n - \hat{b}_n^\dagger). \quad (\text{A}\cdot 19b)$$

Thus, the physical vacuum is defined as

$$\hat{b}_n |0\rangle = 0. \quad (\text{A}\cdot 20)$$

In short, the diagonalization studied to this point is realized by introducing the generalized Bogoliubov transformation,

$$\hat{b}_n = \sum_{m=0}^{\infty} \left[C_{nm} \hat{a}_m + S_{nm} \hat{a}_m^\dagger \right], \quad (\text{A}\cdot 21a)$$

$$\hat{b}_n^\dagger = \sum_{m=0}^{\infty} \left[C_{nm} \hat{a}_m^\dagger + S_{nm} \hat{a}_m \right]. \quad (\text{A}\cdot 21b)$$

Here the real matrices C and S in the matrix notation are given by

$$C = \frac{1}{2} \left(E^{\frac{1}{2}} \mathcal{O} \epsilon^{-\frac{1}{2}} + E^{-\frac{1}{2}} \mathcal{O} \epsilon^{\frac{1}{2}} \right), \quad (\text{A}\cdot 22\text{a})$$

$$S = \frac{1}{2} \left(E^{\frac{1}{2}} \mathcal{O} \epsilon^{-\frac{1}{2}} - E^{-\frac{1}{2}} \mathcal{O} \epsilon^{\frac{1}{2}} \right), \quad (\text{A}\cdot 22\text{b})$$

with E defined by (A.12) and

$$(\epsilon)_{nm} = (\epsilon_n + \varepsilon \bar{\epsilon}) \delta_{nm}. \quad (\text{A}\cdot 23\text{a})$$

One can easily check the properties of C and S from Eq. (A.22), and we find

$$\sum_{m=0}^{\infty} (C_{nm} C_{n'm} - S_{nm} S_{n'm}) = \delta_{nn'}, \quad (\text{A}\cdot 24\text{a})$$

$$\sum_{m=0}^{\infty} (C_{nm} S_{n'm} - S_{nm} C_{n'm}) = 0. \quad (\text{A}\cdot 24\text{b})$$

Thus, the field operators can be expanded in terms of $\hat{b}$ -operators diagonalizing the Hamiltonian $\hat{H}_{\text{MFA}}$ as

$$\hat{\varphi}(x) = \sum_{n=0}^{\infty} [\hat{b}_n e^{-iE_n t} w_{Cn}(\mathbf{x}) - \hat{b}_n^\dagger e^{iE_n t} w_{Sn}(\mathbf{x})], \quad (\text{A}\cdot 25\text{a})$$

$$\hat{\varphi}^\dagger(x) = \sum_{n=0}^{\infty} [\hat{b}_n^\dagger e^{iE_n t} w_{Cn}(\mathbf{x}) - \hat{b}_n e^{-iE_n t} w_{Sn}(\mathbf{x})], \quad (\text{A}\cdot 25\text{b})$$

with

$$w_{Cn}(\mathbf{x}) = \sum_{m=0}^{\infty} C_{nm} w_m(\mathbf{x}), \quad (\text{A}\cdot 26\text{a})$$

$$w_{Sn}(\mathbf{x}) = \sum_{m=0}^{\infty} S_{nm} w_m(\mathbf{x}). \quad (\text{A}\cdot 26\text{b})$$

It is emphasized that the canonical commutation relation

$$[\hat{\varphi}(\mathbf{x}, t), \hat{\varphi}^\dagger(\mathbf{x}', t)] = \delta^{(3)}(\mathbf{x} - \mathbf{x}') \quad (\text{A}\cdot 27)$$

holds in this quantization scheme. This is because we introduced the artificial interaction (2.3) so that we could control the infrared divergence, as seen in Eqs. (A.13), (A.21) and (A.22).
